AN  
INAUGURAL DISSSERTATION  
ON

*Secale Cornutum.*

SUBMITTED TO THE  
PRESIDENT, BOARD OF TRUSTEES, AND MEDICAL FACULTY  
OF THE  
UNIVERSITY OF NASHVILLE,  
FOR THE DEGREE OF  
**DOCTOR OF MEDICINE.**

BY  
*Samuel C. D. Bain*

*Nashville Tennessee.*

W. T. BERRY & CO.,  
BOOKSELLERS AND STATIONERS,  
NASHVILLE, TENN.

## Secale Cornutum.

Since the first discovery of this substance, there has existed a great diversity of opinion as to its nature. Some have made it depend on atmospherical changes, or local influences, such as long-continued rains, fogs and noxious dews, or on too poor or humid a soil; by others it was considered as being produced by the puncture of certain insects. But it is now generally conceded to be a parasitic plant, of the order fungi. It grows on the ear of rye, barley, and wheat. From its peculiar shape, it has been called spurred, because of its resemblance to the spur of a cock. And because it is most abundant in rye, it is called Secale cornutum horned or spurred rye.

By N. Léveillé in a memoir published

by him in 1826. in the annals of the  
Linnean Society of Paris, it was announced,  
that it was in reality an altera-  
tion of the grain, and was produced  
by the presence of a parasitic fungus  
which he named *Sphacelia Segetum*, inten-  
ding to signify by this title both the  
color of the diseased grain and the sad  
consequences which result from its  
use when mixed with bread. According  
to Mr Ducket of London, the beginning  
of the growth of ergot, is marked by  
the appearance about the young grain  
and its appendages, of multitudes of  
minute filaments, like cobwebs which  
run over all its parts, cementing anthers  
and stigmas together, and of a white  
coating on the surface of the grain.  
from which on immersion in water

innumerable particles separate, and after a time sink in the fluid. These particles when examined by the microscope prove to be the reproductive agents, germs or sporidia of a species of fungus, and may be observed to sprout and propagate in various ways under proper circumstances. The filaments are the results of the growth of these singular germs. At first it is invisible but it soon increases in size, and breaks through the envelope of the grain, while the perisperm, which was very small and white assumes a violet hue, then elongates or grows, and becomes hard and brittle escaping from between the husk and pushing before it the fungus found at its free extremity. This

4

fungus is soft and yellow, of a disagreeable odor and a sweetish taste. This fungus is rarely met with on the ergot of the shops, being detached either in the gathering, or by friction against each other. This may explain why the ergot so often proves worthless when administered. Therefore great care should be exhibited in the choice of this article. Those grains should be rejected which are smooth and brilliant externally, as well as those having numerous deep fissures, for the one has been deprived of its rounded portion by friction and the other altered by successive rains. The preference should be given to those grains which still retain the fungus on their summit and the

surfaces of which are entire of a violet color and dirty aspect, and covered as it were by powder. It is most abundant on rye which has been sown late in the season in low moist situations, particularly when a hot dry summer succeeds a rainy spring. Bread made from this kind of rye has a nauseous acrid taste and produces numerous fatal diseases, as spasm, extreme dibility and mortification of the extremities. At various periods the most alarming consequences have followed the use of bread made of this diseased grain, amongst the poor of France & England. It is said to have been equally fatal to brutes & fowls when fed on it by way of experiment. The ergot is found projecting from.

among the leaves of the spike, or ear  
it is a long crooked exsertion resembling  
the spur of a cock, pointed at  
its extremity, of a dark brown or vio-  
let color externally and white within  
some of the spikes are occupied wholly  
by spurs, while others have two or three  
only, interspersed with the genuine  
grains of rye.

The medicinal prop-  
erties of this singular substance were  
first made known to the public by  
Dr John Stearns of Saratoga County  
New York in the year 1814 in a letter  
to Dr Ackerly, in which its powers,  
ad partum accelerandum, were extolled  
Empiricum was every where in posse-  
sion of this article, long before they  
ever thought of using it in New York

The German name Mutterkorn literally signifies womb grain or uterine rye. It is natural thence to conclude that a peculiar action on the womb was recognised in it and that it was used from the remotest times. We find that ergot was long used in Germany as a sovereign remedy in floodings.

Its use is far from being new to the midwives of France & Italy as being good in accelerating parturition. Ergot yields its virtues to water & alcohol. Long boiling impairs its properties. The aqueous infusion or decoction is claret-coloured, and has an acid reaction. Nitrate of silver, tincture of gall, acetate & subacetate of lead precipitate it. Ergot has been analyzed by a number of chemists. Wiggles obtained a

peculiar principle which he denominated ergotin, under the impression that it was the active principle. It was obtained by digesting ergot in ether and afterwards in alcohol evaporating the alcoholic solution and treating the extract thus obtained with water, which left the ergotin undissolved. It was of a reddish-brown color, a peculiar nauseous odour and a bitter slightly acrid taste soluble in alcohol but, insoluble in water or ether. The same course has been followed by other chemists but, not with equal success. Wiggers is not thought to be justifiable in appropriating the name of ergotin to the substance until further researches have been made. The active principle is most

generally thought to reside in its fixed oil. Ergot should be kept in well stopped bottles, secure from light & moisture. It is sometimes attacked by a minute worm which consumes the interior leaving only the shell & excrementitious matter. A small quantity of camphor placed at the bottom of the vial is said to guard it against the depredations of these animals. Though ergot may be preserved many years without its virtues deteriorating, yet it is best to renew it every two or three years lest by some accident it may have lost its virtues.

#### Therapeutical Action.

The action of this medicine is too well ascertained at the present time

11

to permit it any longer to be called in question. As a partur accelerator it stands at the head of the list in the *materia medica*, and is capable of producing the most judicious results in the hands of judicious men and alike competent to the development of sad results when ignorant ly or recklessly employed. It is known & acknowledged to stand at the head of those remedies which exercise their specific influence upon the womb. It is perhaps the only medicine which acts specifically upon that organ in producing its contraction. The most celebrated obstetricians both abroad & at home are its most powerful advocates. In large quantities it often produ-

causes nausea & vomiting, and in very large doses it produces giddiness, dilatation of the pupils and even stupor, proving that it also possesses narcotic properties. In small quantities it has no obvious effect upon the male, but when much of it is taken it has been known to be productive of very disastrous consequences, gangrene of the extremities has frequently been the result of its excessive use. Ergot is now recommended by accouchers for arousing or accelerating the uterine contractions during travail, & for preventing or remedying the inertia of the womb, and the hemorrhage which so often accompanies it, after delivery. After its administration the uterine actions are observed to become

more active in the course of ten or fifteen minutes, and if previously slow and feeble, to become more frequent & energetic, and reappearing if before suspended. The contractions of the womb under the effects of this medicine unlike those which attend natural labour have a peculiar character, and cannot be mistaken. The uterine globe remains hard & contracted as soon as the action is felt, the pains are continual instead of intermittent, though there are moments when the patient does not seem to suffer at all, yet if the hand be placed over the abdomen, the womb will still be found to be hard & contracted and there is not that regular succession of repose & contraction which

13

is constantly observed when the travail is spontaneous. The accouchment is ordinarily terminated in from an hour to an hour & a half after its exhibition, but its action soon wears away after that period, and therefore if there is any necessity for its further use, it must be again renewed. When it proves wholly ineffectual the result is ascribable to idiosyncrasy of the individual, or inferiority in the preparation employed. On account of the continued contraction which this medicament produces upon the uterus it should never be administered when the os uteri is undilatable, otherwise there would be danger of injuring the child from the incipient pressure.

1

which is maintained by the organ under its influence. Such has been the observation of numerous practitioners, and the death of the infant has in all probability been frequently caused by its injudicious employment. It has been maintained by many that since its introduction, the number of still-born children has been augmented, and that observation has sufficiently shown, that where it is given to expedite delivery more or less danger always accrues to the offspring; either by the induction of asphyxia, or of positive death, owing to the violence of the contractions of the uterus, or by the deleterious agency of ergot on the foetus. But even were we to admit its prejudicial effect

15

on the foetus in utero to be true, and it has been disproved to by many obstetricians - and that the number of still-born is greater than formerly which however appears to be by no means the case - its influence could be but small, and could not account for the statistical differences that have been noticed. In many cases ergot has been largely administered, and yet the child has been born alive. The pelvis should be well formed the child presenting either by its cephalic or pelvic extremity, and its position well ascertained, before this powerful drug is administered by any physician, it should also be known that no serious obstacle exists within the vagina at the uterine orifice or

at the external parts; that is to say where the cervix uteri is sufficiently dilated or at least soft supple, and patulous enough to admit of dilation, and where the membranes are ruptured. On the other hand its administration should be avoided as much as possible in primaparae, and if at any time its use should be determined on, or thought to be indispensable in them, the perineum must be supported with the greatest care, lest if the delivery should prove rapid, it be exposed to a considerable rupture. The cases to which it is thought to be especially adapted are those of longing labour, where the os uteri is sufficiently dilated, and the external parts sufficiently relaxed, when no

mechanical impediment is offered to  
the passage of the child, and the <sup>debility</sup> ascribable only to a want of energy  
in the uterus. A slowness or feeble-  
ness of the contractions may occur at  
the very commencement of the labour,  
and persist throughout its whole  
duration; the pains are quite feeble  
the dilatation of the os uteri is effected  
but very slowly, and the engagement of  
the head is trifling; and this delay  
is owing to a local disposition of the  
womb, the determining causes should  
be carefully sought after, and if they  
be owing to a debility, or an imperfect  
organization of the uterus itself, though  
the patient may be otherwise healthy  
that is the muscular apparatus of the  
womb may be deficient in contractile

18

force, while the other muscles of the organism are endowed with their usual energy; and hence the dilatation of the os uteri is effected slowly for notwithstanding the cervix no longer <sup>offers</sup> any resistance, the organ appears incapable of determining the expulsion of the foreign body it encloses. In such cases the ergotized rye is the only article capable of stimulating the enfeebled contractions.

It is not at all unusual, to find a labour which has heretofore been progressing favourably to become at once arrested, and the pains which up to that time were strong & frequent, to become relaxed or even to disappear altogether; when this cessation of the pains, can be ascribed to debil-

ity of the womb itself, since there are some women in whom the contractile force of this organ is so easily exhausted, that the contractions after having proved quite sufficient for the earlier steps of the labour diminish or disappear all at once without any other appreciable cause than this extreme feebleness of the womb.

In all such cases there is nothing which will prove so highly serviceable to bring on the pains and restore the contractile power of the womb as a full dose of ergot. The circumstances justifying and forbidding the use of ergot in parturition ~~are~~ well marked out that no man need err in its administration. If the os uteri be at all dilated or in a

dilatable state, the proper uterine contractions being wanting, the ergot may be safely administered, and most happy effects will follow its exhibition. But if the uterine contractions be pretty strong & regular, the os uteri undilatable; and every feature of the case indicating the use of the lancet, the administration of ergot will be of no avail, and can do nothing but harm to the patient, by producing a rupture of the uterus.

One of the latest writers on parturition (W. Tyler Smith M.D.) says  
"Ergot is a medicine of direct, and not of spinal reflex action. It is of extreme value in cases in which from the state of the passages, there is no danger of laceration or rupture. Its

action on the uterus through the spinal centre, is as special as the influence of tartar emetic on the respiratory muscles." On account of the influence of ergot on the life of the child either as a direct poison, or by interfering with the materno-fetal circulation, it should not be used until the usual reflex modes of exciting the uterus to action had been tried in vain. It has long been a question of debate whether ergot which possesses in so high a degree the property of stimulating the enfeebled contractions & of arousing them when suspended, whether can it develop them when they have not yet existed? Although it has been doubted by some of the most eminent obstetricians and even

denied by some, that ergot possesses this power, yet the profession are gradually becoming convinced and forced to acknowledge that it is able to bring on these contractions, and that it exerts its specific influence upon the uterus, without having previously been brought into action by the natural contractions of the womb. For the purpose of inducing premature labour, it has been necessary to give it in larger doses, from two to twelve drachms of the infusion have been given until it produced the desired effect.

In menorrhagia where the texture of the womb is in a lax & flaccid condition, of all remedies the most clearly indicated is

the scale cornutum, because if <sup>it has</sup> any effect whatever upon the non gravid womb, it would be the effect of condensing the uterine solids, for if the womb in its substance, shall become condensed all its parts will receive the benefits of that condensation. A few doses of the ergot will frequently put an end to the menorrhagia & is always a good and safe remedy in that complaint. The excito-uterine action of ergot has also been shown in suspension of the menses, which it will often cause to return in a few days as has been shown in a number of instances. The effect of ergot in expulsion of uterine polypi is also worthy of notice. The polypi being

foreign bodies within the womb  
the contractions induced by the ergot  
breaks off the connections from the  
womb & causes the maz to be expelled  
Its haemostatic powers are conclusively  
shown in the successful treatment of  
epistaxis, haematemesis & haemoptysis  
and many cases have been published  
in confirmation of its possessing  
such virtues. And again as it proved  
useful in uterine hemorrhages it was  
conceived that it might exhibit like  
powers in other hemorrhages, and  
was found useful in leucorrhœa.  
gonorrhœa dysuria &c. The narcot-  
ic or sedative property, which it exhib-  
its in certain cases & doses, and the  
sedative action which it exerts in oth-  
ers may render it serviceable in

these affections, whatever may have been the process of reasoning which originally led to its employment. It is said to give rise to profuse sloughing ~~of the~~ when applied to abraded surfaces, placed upon wounds nearly healed it has caused a purulent matter to be discharged in less than twenty four hours; and the wounds thus treated even under the proper curative means are very long and tedious in healing. In the form of powder it has been found very serviceable in arresting hemorrhage, even in the form of infusion it possesses the power in an extraordinary degree lint dipped in the infusion and placed on the orifices of bleeding vessels, has instantly arrested the

hemorrhage. Excessive dilatation of the eyes from the use of belladonna is said to disappear if the pulverized ergot be used as a snuff.
